

# Modelling in CP

# Formalization as a Constraint Satisfaction Problem (CSP)

- A CSP is a triple  $\langle X, D, C \rangle$  where:
  - $X$  is a set of decision variables  $\{X_1, \dots, X_n\}$ ;
  - $D$  is a set of domains  $\{D_1, \dots, D_n\}$  for  $X$ :
    - $D_i$  is a set of possible values for  $X_i$ ;
    - usually non-binary and assume finite domain;
  - $C$  is a set of constraints  $\{C_1, \dots, C_m\}$ :
    - $C_i$  is a relation over a subset of variables  $\{X_j, \dots, X_k\}$ , denoted as  $C_i(X_j, \dots, X_k)$ , which is a set of combinations of allowed values of the variables  $C_i \subseteq D(X_j) \times \dots \times D(X_k)$ .
- A **solution** to a CSP is an assignment of values to the variables which satisfies all constraints simultaneously.

# Constraint Optimization Problems

- CSP enhanced with an optimization criterion, e.g.:
  - minimum cost;
  - shortest distance;
  - fastest route;
  - maximum profit.
- Formally,  $\langle X, D, C, f \rangle$  where  $f$  is the formalization of the optimization criterion as an objective variable. Goal: minimize  $f$  (maximize  $-f$ ).

# N-Queens

- Place  $n$  queens in an  $n \times n$  board so that no two queens can attack each other.

# N-Queens

- **Variables and Domains**

- A variable for each row  $[X_1, X_2, \dots, X_n] \rightarrow$  no row attack
- Domain values  $[1..n]$  represent the columns:
  - $X_i = j$  means that the queen in row  $i$  is in column  $j$

- **Constraints**

- **alldifferent** $([X_1, X_2, \dots, X_n]) \rightarrow$  no column attack
- for all  $i < j$   $|X_i - X_j| \neq |i - j| \rightarrow$  no diagonal attack

Diagram illustrating a 9x9 Sudoku grid. The grid is divided into 3x3 sub-grids. The variables  $X_{11}$ ,  $X_{19}$ ,  $X_{91}$ , and  $X_{99}$  are shown with red arrows pointing to their respective cells in the grid.

- **Variables and Domains**

- 9x9 variables  $X_{ij}$  for each cell with domains [1..9].
  - $X_{ij} = k$  means that the cell  $X_{ij}$  has the value  $k$ .

- **Constraints**

- Initial assignments. E.g.,  $X_{21} = 6$ .
- Difference constraints on all the rows, columns, and 3x3 boxes. E.g.,
  - $\text{alldifferent}([X_{11}, X_{21}, X_{31}, \dots, X_{91}])$
  - $\text{alldifferent}([X_{11}, X_{12}, X_{13}, \dots, X_{19}])$
  - $\text{alldifferent}([X_{11}, X_{21}, X_{31}, X_{12}, X_{22}, X_{32}, X_{13}, X_{23}, X_{33}])$

# Task Scheduling

- Schedule  $n$  tasks on a machine, in time  $D$ , by obeying the temporal and precedence constraints:
  - each task  $t_i$  has a specific fixed processing time  $p_i$ ;
  - each task  $t_i$  can be started after its release date  $r_i$ , and must be completed before its deadline  $d_i$ ;
  - tasks cannot overlap in time;
  - precedence relations ( $\rightarrow$ ) must be respected.

# Task Scheduling

- Variables and Domains

- $\text{Start}_i$ , representing the starting time of a task  $t_i$ , taking a value from  $[0..D]$ .
- Ensures that each task starts at exactly one time point.

- Constraints

- Respect of release date and deadline
  - for all  $i \in \{1, \dots, n\}$ ,  $r_i \leq \text{Start}_i \leq d_i - p_i$
- No overlap in time
  - **noOverlap**( $[\text{Start}_1, \dots, \text{Start}_n]$ ,  $[p_1, \dots, p_n]$ )
- Precedence constraints
  - $\text{Start}_i + p_i \leq \text{Start}_j$  for each pair of tasks  $t_i \rightarrow t_j$

# Optimal Map Colouring

- What is the minimum number of colours necessary to colour the neighbouring regions differently?

# Optimal Map Colouring

- **Variables and Domains**
  - $X_i$  for each of  $n$  regions with domain  $[1..n]$ .
- **Constraints**
  - $X_i \neq X_j$  for each neighbour region  $i$  and  $j$
- **Objective variable**
  - $f = \max(X_i)$
- **Objective:** minimize  $f$

# Variables and Domains

- Variable domains include the classical:
  - binary, integer, continuous.
- In addition, variables may take a value from *any* finite set.
  - e.g.,  $X$  in  $\{a,b,c,d,e\}$ .
- There exist special “structured” variable types.
  - Set variables (take a set of elements as value).
  - Activities or interval variables (for scheduling applications).

# Constraints

- Any constraint can be expressed by listing all the allowed combinations.
  - E.g.,  $C(X_1, X_2) = \{(0,0), (0,2), (1,3), (2,1)\}$
  - **Extensional** representation.
  - General but possibly inconvenient and inefficient with large domains.
- Declarative (invariant) relations among objects.
  - E.g.,  $X > Y$
  - **Intensional** representation.
  - More compact, clear but less general.

# Properties of Constraints

- The order of imposition does not matter.
  - $X + Y \leq Z$  is the same as  $Z \geq X + Y$ .
- Non-directional.
  - A constraint between  $X$  and  $Y$  can be used to infer domain information on  $Y$  given domain information on  $X$  and vice versa.
- Rarely independent.
  - Shared variables as communication mechanism between different constraints.

# Constraints – Examples

- Algebraic expressions

- $X_1 > X_2$
- $X_1 + X_2 = X_3$

- Logical expressions

- $X \wedge Y \rightarrow Z$

- Global constraints

- **alldifferent**( $[X_1, X_2, X_3]$ ) instead of:

$$X_1 \neq X_2, X_1 \neq X_3, X_2 \neq X_3$$

- **noOverlap**( $[Start_1, \dots, Start_n], [p_1, \dots, p_n]$ ) instead of:

for all  $i < j \in \{1, \dots, n\}$ ,  $(Start_i + p_i \leq Start_j) \vee (Start_j + p_j \leq Start_i)$

# Constraints – Examples

- Variables as subscripts (**element** constraints)
  - $Y = \text{cost}[X]$  (here  $Y$  and  $X$  are variables, 'cost' is an array of parameters)
- Meta-constraints
  - $\sum_i (X_i > t_i) \leq 5$
- Extensional constraints (**table** constraints)
  - $(X, Y, Z) \in \{(1, 2, 2), (2, 3, 3), (1, 2, 3)\}$

# Modeling is Critical!

- **Choice of variables and domains** defines the search space size:
  - $|D(X_1)| \times |D(X_2)| \times \dots \times |D(X_n)|$ ;
  - Exponential in size!
- **Choice of constraints** defines:
  - how search space can be reduced;
  - how search can be guided.
- Need to go beyond the declarative specification!

# Modeling is Critical

- Given the human understanding of a problem, we need to answer questions like:
  - which variables shall I choose?
  - which constraints shall I enforce?
  - can I exploit any global constraints?
  - do I need any auxiliary variables?
  - are some constraints redundant, therefore can be avoided?
  - are there any implied constraints?
  - can symmetry be eliminated?
  - are there any dual viewpoints?
  - among alternative models, which one shall I prefer?

# Golomb Ruler

- Place  $m$  marks on a ruler such that:
  - distance between each pair of marks is different;
  - the length of the ruler is minimum.
- Applications in radio astronomy and information theory.
- Difficult to solve! Largest known ruler is of order 28.

A non optimal Golomb ruler of order 4.

# Golomb Ruler

- Place  $m$  marks on a ruler such that:
  - distance between each pair of marks is different;
  - the length of the ruler is minimum.
- Applications in radio astronomy and information theory.
- Difficult to solve! Largest known ruler is of order 28.

An optimal Golomb ruler of order 4.

# Naive Model

- Variables and Domains

- $[X_1, X_2, \dots, X_m]$
- $X_i$ , representing the position of the  $i^{\text{th}}$  mark, taking a value from  $\{0, 1, \dots, 2^{(m-1)}\}$

# Naive Model

- Variables and Domains
  - $[X_1, X_2, \dots, X_m]$
  - $X_i$ , representing the position of the  $i^{\text{th}}$  mark, taking a value from  $\{0, 1, \dots, 2^{(m-1)}\}$
- Constraints
  - for all  $i_1 < j_1, i_2 < j_2, i_1 \neq i_2$  or  $j_1 \neq j_2$   $|X_{i_1} - X_{j_1}| \neq |X_{i_2} - X_{j_2}|$
- Objective: minimize  $(\max([X_1, X_2, \dots, X_m]))$

# Naive Model

- **Variables and Domains**
  - $[X_1, X_2, \dots, X_m]$
  - $X_i$ , representing the position of the  $i^{\text{th}}$  mark, taking a value from  $\{0, 1, \dots, 2^{(m-1)}\}$
- **Constraints**
  - for all  $i_1 < j_1, i_2 < j_2, i_1 \neq i_2$  or  $j_1 \neq j_2$   $|X_{i_1} - X_{j_1}| \neq |X_{i_2} - X_{j_2}|$
- **Objective:** minimize  $(\max([X_1, X_2, \dots, X_m]))$
- Problematic model.
  - Quartic  $O(m^4)$  quaternary constraints.
  - Loose reduction in domains.

# Better Model

- **Auxiliary Variables**

- New variables introduced into a model, because either:
  - it is difficult/impossible to express some constraints on the main decision variables;
  - or some constraints on the main decision variables do not lead to significant domain reductions.
- for all  $i < j$   $D_{ij}$ , representing the distance between  $i^{\text{th}}$  and the  $j^{\text{th}}$  marks.

- **Constraints**

- for all  $i < j$ ,  $D_{ij} = |X_i - X_j|$
- **alldifferent**( $[D_{12}, D_{13}, \dots, D_{(m-1)m}]$ )

# Better Model

- Constraints

- for all  $i < j$   $D_{ij} = |X_i - X_j|$
- **alldifferent**( $[D_{12}, D_{13}, \dots, D_{(m-1)m}]$ )

- Improvements

- Quadratic  $O(m^2)$  ternary constraints.
- A global constraint.

# Better Model

- Constraints

- for all  $i < j$   $D_{ij} = |X_i - X_j|$
- alldifferent( $[D_{12}, D_{13}, \dots, D_{(m-1)m}]$ )
- alldifferent( $[X_1, X_2, \dots, X_m]$ )

- Improvements

- $O(m^2)$  ternary constraints.
- A global constraint.
- Implied constraint
  - Logically implied by the constraints defining the problem which cannot be deduced by the solver.
  - Semantically redundant (no change in the set of solutions),  
computationally significant (can greatly reduce the search space)!

# Symmetry in CSPs

- Creates many symmetrically equivalent search states:
  - a state leading to a solution/failure will have many symmetrically equivalent states.
- Bad when proving optimality, infeasibility or looking for all solutions.
  - May lead to thrashing.
- Variable and value symmetry.

# Symmetries and Permutation

- Variable Symmetry
  - A permutation  $\pi$  of the variable indices s.t. for each (un)feasible assignment, we can re-arrange the variables according to  $\pi$  and obtain another (un) feasible assignment.
  - Intuitively: permuting variable assignments.
  - $\pi$  identifies a specific symmetry.

# Variable Symmetries in Golomb Ruler

- Permuting variable assignments

$$X_1 = 0, X_2 = 1, X_3 = 4, X_4 = 6$$

$$X_1 = 0, X_2 = 1, X_3 = 6, X_4 = 4$$

$$X_1 = 0, X_2 = 4, X_3 = 1, X_4 = 6$$

$$X_1 = 0, X_2 = 4, X_3 = 6, X_4 = 1$$

$$X_1 = 0, X_2 = 6, X_3 = 1, X_4 = 4$$

$$X_1 = 0, X_2 = 6, X_3 = 4, X_4 = 1$$

...

- $m!$  permutations  $\rightarrow m!$  variable symmetries.
- For a given (un)feasible assignment, there are  $m!$  (un)feasible assignments.

# Value Symmetry

- Value Symmetry
  - A permutation  $\pi$  of values s.t. for each (un)feasible assignment, we can re-arrange the values according to  $\pi$  and obtain another (un) feasible assignment.
  - Intuitively: permuting values.
  - $\pi$  identifies a specific symmetry.

# A Value Symmetry in Golomb Ruler

- Values can be permuted as:

$0 \rightarrow 0, 1 \rightarrow 2, 2 \rightarrow 1, 3 \rightarrow 3, 4 \rightarrow 5, 5 \rightarrow 4, 6 \rightarrow 6$   
(reversing the ruler)

$X_1 = 0, X_2 = 1, X_3 = 4, X_4 = 6 \rightarrow$

$X_1 = 0, X_2 = 2, X_3 = 5, X_4 = 6$

**Any other value symmetry in the models we have seen so far?**

# Variable and Value Symmetry

- Composition of a variable and a value symmetry.
- Golomb Ruler
  - Both variable assignments and values can be permuted.  
$$X_1 = 0, X_2 = 1, X_3 = 4, X_4 = 6 \rightarrow X_1 = 0, X_2 = 2, X_3 = 5, X_4 = 6$$
$$\rightarrow X_1 = 2, X_2 = 0, X_3 = 6, X_4 = 5$$
  - For a given (un)feasible assignment, there are  $2^m$  (un)feasible assignments.

# Symmetry Breaking Constraints

- Reduce the set of solutions and search space!
- Not implied by the constraints defining the problem.
- Common technique: impose an ordering to avoid permutations.
  - E.g.,  $X_1 \leq X_2 \leq \dots \leq X_n$  when  $[X_1, X_2, \dots, X_n]$  are all symmetric.
- **Attention:** at least one solution from each set of symmetrically equivalent solutions must remain.

# Improved Model

- Symmetry Breaking Constraints
  - $X_1 < X_2 < \dots < X_m$
  - $X_1 = 0$
  - $D_{12} < D_{(m-1)m}$
- New objective
  - minimize  $(X_m)$

# Improved Model

- Symmetry breaking constraints enable **constraint simplification**.
  - $X_1 < X_2 < \dots < X_m$ 
    - **alldifferent**( $[X_1, X_2, \dots, X_m]$ ) becomes **redundant** (semantically and computationally).
    - for all  $i < j$ ,  $D_{ij} = |X_i - X_j|$  becomes for all  $i < j$ ,  $D_{ij} = X_j - X_i$
  - Note the terminology redundant vs implied.

# Improved Model

- Symmetry breaking constraints enable additional **implied constraints**.

– for all  $i < j < k$ ,  $D_{ij} < D_{ik}$  and  $D_{jk} < D_{ik}$   
 $D_{ik} = D_{ij} + D_{jk}$

An optimal Golomb ruler of order 4.

# Can We Improve This Model Too?

- **Variables and Domains**

- A variable for each row  $[X_1, X_2, \dots, X_n] \rightarrow$  no row attack
- Domain values  $\{1, \dots, n\}$  represent the columns:
  - $X_i = j$  means that the queen in row  $i$  is in column  $j$

- **Constraints**

- **alldifferent** $([X_1, X_2, \dots, X_n]) \rightarrow$  no column attack
- for all  $i < j$   $|X_i - X_j| \neq |i - j| \rightarrow$  no diagonal attack

# N-Queens

- Diagonal attack constraint

- for all  $i < j$   $|X_i - X_j| \neq |i - j|$

- $\equiv$  for all  $i < j$   $X_i - X_j \neq i - j$  and  $X_i - X_j \neq j - i$  and  
 $X_j - X_i \neq i - j$  and  $X_j - X_i \neq j - i$

- $\equiv$  for all  $i < j$   $X_i - i \neq X_j - j$  and  $X_i + i \neq X_j + j$

- $\equiv$  **alldifferent**( $[X_1 - 1, X_2 - 2, \dots, X_n - n]$ )

- $\equiv$  **alldifferent**( $[X_1 + 1, X_2 + 2, \dots, X_n + n]$ )

# A Better Model for N-Queens

- Original Model

- `alldifferent`([ $X_1, X_2, \dots, X_n$ ])  $\rightarrow$  no column attack
- for all  $i < j$   $|X_i - X_j| \neq |i - j|$   $\rightarrow$  no diagonal attack

- Alldiff Model

- `alldifferent`([ $X_1, X_2, \dots, X_n$ ])
- `alldifferent`([ $X_1 + 1, X_2 + 2, \dots, X_n + n$ ])
- `alldifferent`([ $X_1 - 1, X_2 - 2, \dots, X_n - n$ ])

# Modeling is Critical!

- Given the human understanding of a problem, we need to answer questions like:
  - which variables shall I choose?
  - which constraints shall I enforce?
  - can I exploit any global constraints?
  - do I need any auxiliary variables?
  - are some constraints redundant, therefore can be avoided?
  - are there any implied constraints?
  - can symmetry be eliminated?
  - are there any dual viewpoints?
  - among alternative models, which one shall I prefer?

# Dual Viewpoint

- Viewing a problem **P** from different perspectives may result in different models.
- Each model yields the same set of solutions.
- Each model exhibits in general a different representation of **P**.
  - Different variables.
  - Different domains.
  - Different constraints.
    - Different size of the search space!
- Can be hard to decide which is better!

# Symmetries of N-Queens

- Geometric symmetries.
  - Cannot impose an ordering like  $X_1 \leq X_2 \leq \dots \leq X_n$ 
    - We need to avoid certain 7 permutations of  $[X_1, X_2, \dots, X_n]$ , not all permutations.
  - These permutations are difficult to define in the current model.

# A New Model for N-Queens

- **Variables and Domains**
  - Represent the board with  $n \times n$  Boolean variables  $B_{ij} \in \{0,1\}$ .
- **Attacking Constraints**
  - $\sum B_{ij} = 1$  on all rows and columns,  $\sum B_{ij} \leq 1$  on all diagonals.
- **Symmetry Breaking Constraints**
  - Flatten the 2-d matrix to a single sequence of variables.
    - E.g., append every row to the end of the first row.
  - Every symmetric configuration corresponds to a **variable permutation** of the original solution, which is easy to define.
  - We then impose an order between a solution and all the solutions obtained by the 7 permutations:
    - **lex** $\leq(B, \pi(B))$  for all  $\pi$ .

# Lexicographic Ordering Constraint

- Requires a sequence of variables to be lexicographically less than or equal to another sequence of variables.
- **lex** $\leq$  ( $[X_1, X_2, \dots, X_k], [Y_1, Y_2, \dots, Y_k]$ ) holds iff:
  - $X_1 \leq Y_1$  AND
  - $(X_1 = Y_1 \rightarrow X_2 \leq Y_2)$  AND
  - $(X_1 = Y_1 \text{ AND } X_2 = Y_2 \rightarrow X_3 \leq Y_3) \dots$
  - $(X_1 = Y_1 \text{ AND } X_2 = Y_2 \dots X_{k-1} = Y_{k-1} \rightarrow X_k \leq Y_k)$
- **lex** $\leq$  ( $[1, 2, 4], [1, 3, 3]$ )

# Symmetry Breaking in N-Queens

- $\text{lex} \leq (B, [B_{ji} \mid i, j \in [1..n] ])$
- $\text{lex} \leq (B, [B_{ij} \mid i \in [n..1], j \in [1..n] ])$
- $\text{lex} \leq (B, [B_{ji} \mid i, j \in [n..1] ])$
- $\text{lex} \leq (B, [B_{ij} \mid i \in [1..n], j \in [n..1] ])$
- ...

- $i, j \rightarrow j, i$
- $i, j \rightarrow \text{reverse } i, j$
- $i, j \rightarrow \text{reverse } j, \text{reverse } i$
- $i, j \rightarrow i, \text{reverse } j$
- ...

# Symmetry Breaking in N-Queens

- $\text{lex} \leq (B, [B_{ji} \mid i, j \in [1..n] ])$
  - $\text{lex} \leq (B, [B_{ij} \mid i \in [n..1], j \in [1..n] ])$
  - $\text{lex} \leq (B, [B_{ji} \mid i \in [1..n], j \in [n..1] ])$
  - $\text{lex} \leq (B, [B_{ij} \mid i \in [1..n], j \in [n..1] ])$
  - $\text{lex} \leq (B, [B_{ji} \mid i \in [n..1], j \in [1..n] ])$
  - $\text{lex} \leq (B, [B_{ij} \mid i, j \in [n..1] ])$
  - $\text{lex} \leq (B, [B_{ji} \mid i, j \in [n..1] ])$

# Which Model?

- Alldiff Model

- $[X_1, X_2, \dots, X_n] \in [1..n]$
- alldifferent( $[X_1, X_2, \dots, X_n]$ )
- alldifferent( $[X_1 + 1, X_2 + 2, \dots, X_n + n]$ )
- alldifferent( $[X_1 - 1, X_2 - 2, \dots, X_n - n]$ )

☺ Global constraints

☹ No easy symmetry breaking

- Boolean Symmetry Breaking Model

- $n \times n B_{ij} \in [0..1]$
- $\sum B_{ij} = 1$  on all rows, columns
- $\sum B_{ij} \leq 1$  on diagonals
- lex $\leq$ ( $B, \pi(B)$ ) for all  $\pi$

☺ Easy symmetry breaking

☹ No global constraints

# Which Model?

- Combined model
  - If you can't beat them, combine them 😊
  - Keep both models and use **channeling constraints** to maintain consistency between the variables of the two models.
  - Benefits:
    - Facilitation of the expression of constraints.
    - Enhanced constraint propagation.
    - More options for search variables.

# Combined Model

- **Variables**
  - for all  $i$ ,  $X_i \in [1..n]$ , for all  $i, j$   $B_{ij} \in [0..1]$
- **Constraints**
  - **alldifferent**( $[X_1, X_2, \dots, X_n]$ )
  - **alldifferent**( $[X_1 + 1, X_2 + 2, \dots, X_n + n]$ )
  - **alldifferent**( $[X_1 - 1, X_2 - 2, \dots, X_n - n]$ )
  - **lex** $\leq$ ( $B, \pi(B)$ ) for all  $\pi$
- **Channeling Constraints**
  - for all  $i, j$   $X_i = j \Leftrightarrow B_{ij} = 1$

Do you notice something?

IT TRANSFERRED THE INFORMATION

THANKS TO THE CHANNELING, WE DON'T NEED THE BOOLEAN CONSTRAINTS ANYMORE
